# B.Tech. BCSE497J - Project-I

# Sign Language Recognition System

*Submitted in partial fulfillment of the requirements for the degree of*

## Bachelor of Technology

*in*

## Computer Science and Engineering

*by*

**22BCE0094 AKSHIT GUPTA**

**22BCE2435 ATHARV PRADHAN**

**Under the Supervision of**

**DR. SINTHUJA M**

Associate Professor Grade 1

School of Computer Science and Engineering (SCOPE)

Vellore Institute of Technology

(Deemed to be University under section 3 of UGC Act, 1956)

November 2025

# DECLARATION

I hereby declare that the project entitled **Sign Language Recognition System** submitted by me, for the award of the degree of *Bachelor of Technology in Computer Science and Engineering* to VIT is a record of bona fide work carried out by me under the supervision of **Dr. Sinthuja M**

I further declare that the work reported in this project has not been submitted and will not be submitted, either in part or in full, for the award of any other degree or diploma in this institute or any other institute or university.

Place: Vellore
Date: 5th November 2025

Akshit

**Signature of the Candidate**

# CERTIFICATE

This is to certify that the project entitled **Sign Language Recognition System** submitted by **Akshit Gupta (22BCE0094), School of Computer Science and Engineering**, VIT, for the award of the degree of *Bachelor of Technology in Computer Science and Engineering*, is a record of bonafide work carried out by them under my supervision during Fall Semester 2024-2025, as per the VIT code of academic and research ethics.

The contents of this report have not been submitted and will not be submitted either in part or in full, for the award of any other degree or diploma in this institute or any other institute or university. The project fulfills the requirements and regulations of the University and in my opinion meets the necessary standards for submission.

Place: Vellore
Date: 5th November 2025

**Signature of the Guide**

**Examiner(s)**

**Dr. Boominathan P**

**SCOPE**

# ACKNOWLEDGEMENTS

I am deeply grateful to the management of Vellore Institute of Technology (VIT) for providing me with the opportunity and resources to undertake this project. Their commitment to fostering a conducive learning environment has been instrumental in my academic journey. The support and infrastructure provided by VIT have enabled me to explore and develop my ideas to their fullest potential.

My sincere thanks to **Dr. Jaisankar N**, the Dean of the School of Computer Science and Engineering (SCOPE), for his unwavering support and encouragement. His leadership and vision have greatly inspired me to strive for excellence. The Dean's dedication to academic excellence and innovation has been a constant source of motivation for me. I appreciate his efforts in creating an environment that nurtures creativity and critical thinking.

I express my profound appreciation to **Dr. Boominathan P**, the Head of the SCOPE dept., for his insightful guidance and continuous support. His expertise and advice have been crucial in shaping the direction of my project. The Head of Department's commitment to fostering a collaborative and supportive atmosphere has greatly enhanced my learning experience. His constructive feedback and encouragement have been invaluable in overcoming challenges and achieving my project goals.

I am immensely thankful to my project guide, **Dr. Sinthuja M**, for her dedicated mentorship and invaluable feedback. Her patience, knowledge, and encouragement have been pivotal in the successful completion of this project. My supervisor's willingness to share his/her expertise and provide thoughtful guidance has been instrumental in refining my ideas and methodologies. His/her support has not only contributed to the success of this project but has also enriched my overall academic experience.

Thank you all for your contributions and support.

**Akshit Gupta**

| **Pandas** | Python Data Analysis Library |
| **FPDF2** | Python PDF Generation Library |

# ABSTRACT

The area of recognition in sign language remains a major challenge in computer vision and human-computer interaction, motivated by the demand for smooth communication devices closing gaps for the deaf and hard-of-hearing populations. The proposed project presents a hybrid system combining MediaPipe for landmark recognition with classifiers from Scikit-Learn in order to recognize hand signs in sign language (SL). The system processes real-time live feeds of video, and through the use of OpenCV, performs needed preprocessing and extraction of features, facilitating smooth mapping of alphabetic letters and numeric symbols on dynamic hand poses.

At the heart of the classification pipeline is the Random Forest algorithm, a sturdy ensemble method implemented through Scikit-Learn. Random Forest operates by creating multiple decision trees during training, each on a randomly chosen subset of data and features, and as a whole, voting on the final decision. Overfitting—a characteristic pitfall in gesture recognition work in which variations in hand orientation, illumination, and user-specific techniques contribute noise—is combated by it. Combining the outputs from various trees, Random Forest increases generalization, making it well-equipped to handle the high-dimensional landmark data yielded by MediaPipe. The landmarks, with significant points on the hands such as fingertips and joints, are fed as input features after being normalized and flattened by the image processing utilities in OpenCV.

The project utilizes two open datasets from Kaggle to ensure data quality and diversity for training and evaluation: **Sign Language Alphabet Dataset**, a collection of images for each letter of the sign language alphabet, and **Sign Language Digits Dataset**, containing images for numbers 0 through 9. Additionally, a custom script (*collect_data.py*) is provided to capture and save personalized sign data, allowing expansion of the dataset and improved adaptability to real-world scenarios.

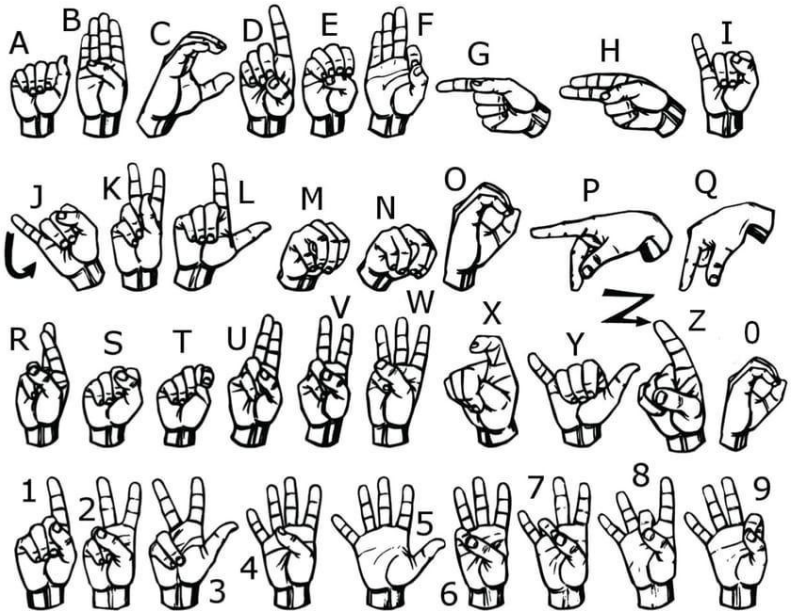
To add practical value, the system goes beyond classification by translating predicted gestures into readable text and synthesized voice output. With this multimodal approach, end-users gain the capability of interacting with devices or communicating in everyday settings without requiring special hardware. The integration of modern pose estimation systems such as MediaPipe with robust methods like Random Forest highlights a balanced and effective route toward inclusive gesture recognition systems.

# 1. INTRODUCTION

## 1.1 Background

Sign language has been an important way of communication for deaf communities for centuries. It started as simple hand gestures and slowly developed into complete languages with their own rules. In the 18th century, people like Abbé de l'Épée helped formalize signs for teaching, creating the base for modern sign languages used across the world. However, even with its long history, sign language has not been easily integrated into daily life because of limited awareness and a lack of translation tools. This inspired researchers to find technological solutions, especially after computers became popular in the mid-1900s. Early systems used gloves or colored markers to track hand movements, but they were uncomfortable and impractical for daily use. Later, camera- based methods became popular, allowing gestures to be recognized naturally. By the early 2000s, statistical models like Hidden Markov Models helped understand sign sequences, though they struggled with continuous gestures.

With the rise of machine learning and deep learning, sign language recognition improved further. Convolutional Neural Networks (CNNs) helped identify hand shapes and movements more accurately, and tools like Microsoft Kinect added 3D sensing to improve detection. In recent years, lightweight libraries such as OpenPose and MediaPipe have made it easier to detect hand and body movements in real time using regular cameras. Traditional algorithms like Support Vector Machines and Random Forests are still useful, especially for static gestures like alphabets and numbers. Our project uses MediaPipe for detecting hand landmarks and Random Forest through Scikit-Learn for classification, with OpenCV for preprocessing. The goal is to build an accessible system that converts gestures into text and speech efficiently, promoting better communication and inclusion for everyone.



## 1.2 Motivations

Communication is the foundation of human connection, yet for millions of people who are deaf or hard of hearing, expressing themselves and being understood often comes with challenges. While sign language is a powerful and expressive medium, the lack of awareness and understanding among the general population often leads to miscommunication and social isolation. This gap emphasizes the need for technology that can recognize and translate sign language into universally accessible forms such as text and speech.

The motivation behind this project is to build an inclusive bridge between the deaf community and the hearing world. Instead of relying on expensive or specialized hardware, the system uses computer vision and machine learning to identify hand gestures through standard cameras. By combining MediaPipe's real-time hand landmark detection with the Random Forest classifier from Scikit-Learn, the project aims to create a practical and robust solution that works effectively under different lighting conditions, hand orientations, and user styles.

The focus of this work is not only on achieving accurate recognition but also on making the system practical for everyday use. Beyond simple classification, it converts recognized signs into both readable text and synthesized speech, ensuring smooth and natural communication for everyone involved. This multimodal approach helps bridge the gap between deaf individuals and those unfamiliar with sign language, making interactions more inclusive and meaningful.

Another important motivation is adaptability. The system is trained using two open-source Kaggle datasets—the ASL Alphabet Dataset and the ASL Digits Dataset—covering a broad range of hand gestures for letters and numbers. Additionally, a built-in data collection script allows users to add their own gestures, enabling the system to learn new signs and adapt to different users over time. This ensures that the model remains flexible and continues to grow with real-world use.

Ultimately, this project represents more than just a technical achievement—it reflects a genuine effort to promote inclusivity and accessibility. By integrating modern tools for pose estimation with proven machine learning techniques, the project aims to break down communication barriers and move closer to a world where technology truly serves everyone equally.

## 1.3 Scope of the Project

The scope of this project extends beyond developing a simple gesture recognition tool—it envisions a practical and inclusive communication system that can function in real-world environments. At its core, the project aims to accurately recognise static hand gestures representing both alphabetic letters and numerical symbols in sign language, and then translate them into text and synthesised speech. This dual output ensures accessibility for a wider audience, enabling smoother interactions between individuals who use sign language and those who do not.

From a technical perspective, the project integrates MediaPipe for real-time landmark detection, OpenCV for preprocessing and feature extraction, and Random Forest as the classifier for robust

prediction. The system is designed to be lightweight, meaning it can run on standard computing devices without the need for expensive or specialised hardware. This expands its usability to schools, workplaces, healthcare settings, and personal communication.

Another important aspect of the scope is dataset diversity. The project makes use of two publicly available Kaggle datasets—one for sign language alphabets and another for digits—while also providing a custom data collection script. This enables continuous dataset expansion and personalisation, giving users the ability to train the model on their own variations of signs. Such adaptability makes the system scalable and applicable across different contexts.

In terms of future possibilities, the project lays the groundwork for advancing toward sentence-level recognition, where sequences of gestures can be understood in context. It also opens doors for integrating regional variations of sign languages, ensuring cultural and linguistic inclusivity. With further development, the system could be embedded into mobile applications, wearable devices, or even integrated with virtual assistants to enhance accessibility on a daily basis.

In summary, the scope of this project is both functional and forward-looking: it provides an immediate solution for letter and digit recognition, while also creating a foundation for richer, more adaptive systems in the future. It is not confined to academic experimentation but seeks to have a real impact by breaking communication barriers and making technology more human-centred.

# 2. PROJECT DESCRIPTION AND GOALS

## 2.1 Literature Review

The field of Automated Sign Language Recognition (SLR) has witnessed significant progress in recent years, with deep learning models driving remarkable improvements in accuracy, efficiency, and contextual understanding. The rapid advancements in computer vision and artificial intelligence have enabled the development of sophisticated architectures capable of handling the unique spatio-temporal complexities of sign language. However, the current body of research also highlights a fundamental trade-off between models optimized for real-time detection and those designed for deep contextual comprehension. This section critically reviews the state-of-the-art models, their strengths, limitations, and contributions to the 2024–2025 research landscape.

Early breakthroughs in SLR were driven by convolutional architectures, particularly Convolutional Neural Networks (CNNs), which demonstrated high accuracy in static sign recognition. Standard 2D-CNNs excel at recognizing isolated handshapes and letters, often achieving near-perfect accuracy on alphabet datasets. Their extension into 3D-CNNs enabled the modeling of both spatial and temporal dimensions, capturing motion patterns essential for sign dynamics. Hybrid models combining CNNs with Long Short-Term Memory (LSTM) networks further enhanced performance by leveraging CNNs for frame-level feature extraction and LSTMs for sequential understanding. Recent innovations, such as attention-based CNN-LSTM hybrids, have strengthened temporal robustness by allowing models to focus on the most relevant segments of a signing sequence. Despite these successes, CNN-based models suffer from inherent limitations. Their computational

intensity restricts scalability for real-time applications, while their reliance on local receptive fields constrains their ability to model long-range dependencies. Consequently, CNNs are often less effective for continuous sign language recognition (CSLR), where global context and grammar must be preserved across extended sequences.

Transformers have emerged as a transformative paradigm in SLR by addressing these limitations through self-attention mechanisms. Unlike CNNs, Transformers capture both local and global dependencies simultaneously, enabling more effective modeling of sign sequences that span entire sentences. Research in 2024 reports significant performance improvements, with VideoMAE, a Transformer-based model, achieving 75.58% accuracy on the WLASL100 benchmark compared to 65.89% by the CNN-based I3D model. The adaptability of Transformers has inspired several custom architectures tailored to the unique requirements of sign language. The Signer-Invariant Conformer combines convolutional layers with self-attention to balance fine-grained local detail extraction with global sequence modeling, ensuring robustness against signer variability. Similarly, the Multi-Scale Fusion Transformer integrates dual temporal streams to simultaneously process fine and coarse details, thereby improving the recognition of complex grammatical structures. However, these advances come at a cost. Transformers are computationally expensive, with quadratic scaling in sequence length, making them resource-intensive and less suitable for deployment in low-power environments such as mobile devices. Moreover, they remain sensitive to unstructured input data, requiring carefully curated features for optimal performance.

Parallel to these developments, object detection frameworks have gained traction for real-time isolated sign recognition. The YOLO (You Only Look Once) family, particularly YOLOv9, has been successfully adapted for SLR due to its ability to process entire frames in a single pass with high speed and accuracy. YOLOv9 integrates mechanisms such as Programmable Gradient Information (PGI) and the Generalized Efficient Layer Aggregation Network (GELAN) to mitigate information bottlenecks and improve feature fusion, resulting in mean Average Precision (mAP) scores between 97–98% on ASL letter datasets. More recently, YOLOv11 in combination with MediaPipe has shown promising results for real-time hand detection, offering a lightweight and efficient solution for practical applications. Despite their impressive real-time capabilities, YOLO models fundamentally function as static frame detectors, limiting their ability to capture temporal motion or grammatical context. Consequently, their use is largely confined to applications such as alphabet recognition or as preprocessing components for more complex CSLR systems.

Beyond these mainstream architectures, novel models such as AulSign represent experimental efforts to bridge the gap between efficiency and contextual depth. AulSign integrates multimodal inputs and custom architectural refinements to address signer variability, complex sentence structures, and the balance between accuracy and inference speed. While still under exploration, such models exemplify the broader trend of combining the strengths of existing paradigms—CNNs for local feature precision, Transformers for global context, and YOLO for real-time adaptability.

In summary, the literature reveals a vibrant and evolving research landscape. CNN-based architectures have set the foundation with strong performance in static recognition, while Transformers now dominate continuous recognition tasks by offering superior contextual modeling. Real-time frameworks like YOLO continue to play a critical role in enabling fast and lightweight deployments, though they lack the temporal depth required for CSLR. The emergence of hybrib

models, such as the Signer-Invariant Conformer, Multi-Scale Fusion Transformer, and AulSign, highlights ongoing efforts to balance accuracy, efficiency, and scalability. Despite these advances, challenges remain in addressing computational costs, signer generalization, and real-time continuous recognition. These gaps define the central research opportunities for the next generation of SLR systems.

## 2.2 Research Gap

Despite significant progress in Sign Language Recognition (SLR), several research gaps remain that limit the scalability, inclusivity, and practicality of current systems. One critical gap lies in the development of hybrid architectures for real-time Continuous Sign Language Recognition (CSLR). Existing models either prioritize efficiency, as seen in detection-based frameworks, or focus on deep contextual understanding through Transformers and Conformers. However, a balanced solution that integrates the speed of lightweight models with the sequential comprehension of advanced architectures is still lacking. Addressing this would enable practical deployment of CSLR systems on mobile and edge devices.

Another major gap concerns the representation of low-resource sign languages. Most benchmark datasets and high-performing models are designed around a limited set of high-resource sign languages, leaving the vast majority of global sign languages underrepresented. This creates a bias in model performance and risks excluding communities whose languages lack large, annotated datasets. Targeted research efforts are therefore required to build inclusive datasets and methodologies that can generalize across diverse, low-resource languages.

Additionally, there is a clear gap in the area of pose-based representations for invariance. While innovations like Relative Quaternion Encoding (RQE) highlight the importance of how pose information is pre-processed, the field still lacks standardized, robust approaches for structuring and normalizing pose data. Improvements at this stage of the pipeline could enhance generalization across different signers, viewpoints, and environments without over-reliance on massive datasets. Advancing pose-based feature engineering, alongside neural architecture design, thus represents a promising research direction to improve the robustness and adaptability of SLR systems.

## 2.3 Objectives

The primary objective of this project is to design and implement a computer vision–based system capable of detecting and translating American Sign Language (ASL) gestures, specifically the alphabet (A–Z) and numbers (0–9), into real-time text and synthesized speech. The system is intended to bridge the communication barrier between the deaf and hearing communities by providing an accessible and user-friendly medium of interaction. In addition to system development, the project aims to conduct a critical review of the 2024–2025 research landscape in Sign Language Recognition (SLR). This review evaluates the strengths and limitations of current deep learning models, highlights significant architectural advancements, and identifies persistent challenges such as computational efficiency, generalization, and inclusivity of low-resource sign languages. By aligning technological design with these insights, the project not only seeks to deliver a functional and impactful solution but also to contribute meaningfully to advancing research in the field of SLR, fostering inclusivity and accessibility in human communication.

## 2.4 Problem Statement

The communication gap between Sign Language (SL) users and non-signers continues to impose significant barriers in education, workplaces, and everyday interactions, limiting accessibility and inclusivity for millions of people. While advancements in Sign Language Recognition (SLR) have shown promise, existing technologies remain largely inaccessible due to high costs, reliance on specialized hardware, or their narrow ability to recognize only a limited set of gestures. A major challenge lies in creating a scalable and affordable solution that can run effectively on widely available devices such as smartphones and personal computers. Current systems face several technical limitations, including the lack of diverse and comprehensive datasets, which restricts models from generalizing across varied skin tones, lighting conditions, hand orientations, and backgrounds. Deployment also poses difficulties, as models often rely on heavy dependencies that hinder performance in real-world environments. Additionally, the recognition of signs with similar finger configurations (e.g., “M” vs. “N” or “U” vs. “V”) remains a persistent source of misclassification, while real-time latency continues to affect user experience, particularly during continuous signing. Variability in lighting and shadow conditions further complicates accurate detection. Addressing these challenges requires not only robust model design but also innovative strategies such as data augmentation, transfer learning, lightweight deployment frameworks, temporal modeling, and landmark-based feature extraction. Developing such a solution would democratize access to sign language translation, enabling seamless real-time communication and fostering true inclusivity in society.

## 2.5 Project Plan

The project was developed locally using an **iterative, modular approach**, ensuring that each component—data preprocessing, model training, and user interface—was implemented, tested, and optimized before integration.

**1. Phase 1: Environment Setup & Dependencies**
Configured the local Python environment and installed core dependencies including **OpenCV**, **MediaPipe**, **NumPy**, **Pandas**, and **Scikit-learn**. Verified compatibility across Python versions and ensured GPU acceleration where possible for real-time processing.

**2. Phase 2: Dataset Preparation**
Collected and organized datasets from **Kaggle (ASL Alphabet Dataset and ASL Digits Dataset)**. Implemented a custom **data collection script** to capture additional user-specific gesture samples using the webcam, stored in a structured folder format for training and testing.

**3. Phase 3: Image Preprocessing**
Developed preprocessing functions using **OpenCV** for background removal, grayscale conversion, and image resizing. Applied **MediaPipe Hands** for hand landmark extraction, generating 3D coordinate data points representing 21 key hand joints for each frame.

**4. Phase 4: Feature Extraction & Model Training**
Extracted landmark coordinates as numerical features and trained a **Random Forest Classifier (Scikit-Learn)** to recognize static gestures (alphabets and digits). Conducted hyperparameter tuning to improve accuracy and reduce overfitting, achieving consistent performance across test samples.

**5. Phase 5: Gesture Recognition Pipeline**
Integrated the trained model into a real-time recognition pipeline using the system's webcam. Implemented continuous frame capture, landmark detection (via MediaPipe), and prediction visualization on-screen with bounding boxes and label overlays using **OpenCV**.

**6. Phase 6: Text & Speech Conversion**
Enhanced usability by adding **Text-to-Speech (TTS)** conversion using **pyttsx3**, allowing recognized gestures to be spoken aloud. Implemented dynamic text display to improve readability for users unfamiliar with sign language.

**7. Phase 7: GUI Development**
Created a lightweight **Tkinter-based graphical interface** to simplify user interaction. The interface allows users to start/stop recognition, view detected gestures in real-time, and toggle speech output.

**8. Phase 8: Testing & Optimization**
Performed end-to-end testing for gesture accuracy, latency, and usability. Addressed issues related to varying hand orientations, lighting, and background noise. Optimized the frame processing rate to maintain smooth real-time performance on standard hardware.

**9. Phase 9: Documentation & Deployment**
Compiled project documentation including installation steps, dataset references, and model explanation. Deployed the system locally and verified portability across Windows and Linux environments for future scalability.

# 3. TECHNICAL SPECIFICATION

## 3.1 Requirements

### 3.1.1 Functional Requirements

**User Interface:** The system shall provide a simple graphical interface that allows users to start and stop the webcam feed, view real-time gesture recognition results, and toggle speech output.

● **Gesture Capture:** The system shall capture live video input from a standard webcam to detect hand gestures made by the user.

● **Hand Landmark Detection:** The system shall use **MediaPipe Hands** to detect and extract 21 key hand-landmark points for each frame captured.

● **Preprocessing:** The system shall preprocess captured frames by resizing, normalizing, and filtering coordinates to prepare consistent input for the classification model.

● **Gesture Classification:** The system shall classify detected gestures using a **Random Forest Classifier** trained on the **ASL Alphabet** and **ASL Digits** datasets.

● **Prediction Output:** The recognized gesture shall be displayed on screen as a real-time text label corresponding to the predicted sign.

● **Text Conversion:** The system shall convert the recognized gesture into textual output that updates dynamically as the user performs signs.

● **Speech Output:** The system shall use a **Text-to-Speech (TTS)** engine (e.g., pyttsx3) to convert recognized text into audible speech, enabling communication with non-sign-language users.

● **Custom Data Collection:** The system shall allow users to collect and store new gesture samples through a data collection script, enabling customization and model retraining.

● **Model Training:** The system shall support training or retraining of the classification model using newly collected gesture data, improving personalization and accuracy.

● **Real-Time Recognition:** The system shall perform gesture recognition in real time, maintaining smooth performance and low latency on standard hardware.

● **Error Handling:** The system shall display warnings or messages when no hand is detected, when lighting conditions are poor, or when the gesture is unrecognized.

● **Result Logging:** The system shall log recognized gestures along with timestamps and confidence scores for later analysis or debugging.

● **Dataset Integration:** The system shall integrate open-source datasets such as the **ASL Alphabet Dataset** and **ASL Digits Dataset** for training and testing.

● **Scalability:** The system shall support the addition of new gestures and expansion of the dataset without requiring structural changes to the recognition pipeline.

### 3.1.2 Non-Functional Requirements

● **Security:** The system shall not store or transmit any sensitive user data. All processing (video capture, gesture recognition, and model inference) shall occur locally on the user's device to ensure data privacy. External libraries such as MediaPipe and Scikit-Learn shall be used securely without exposing any API keys or credentials.

● **Usability:** The graphical interface shall be clean, intuitive, and accessible for users of all ages. It shall provide clear visual cues (such as on-screen labels and bounding boxes) and status indicators for recognition results, camera readiness, and system errors.

● **Maintainability:** The project shall be modular and well-structured, separating components into logical modules such as **data_processing**, **feature_extraction**, **model_training**, and **gui_interface**. Each module shall be self-contained and easily replaceable for future upgrades or algorithm changes.

● **Reliability (Local):** The system shall use structured exception handling (`try...except` blocks) to manage common runtime errors, such as camera access failures or missing dependencies. It shall remain operational even if individual frames or gestures fail to process correctly.

● **Performance (Local):** The system shall perform gesture detection and classification in real time, maintaining a frame rate of at least **15–20 FPS** under normal conditions. All computations shall be optimized for CPU execution, ensuring smooth performance on standard consumer laptops without requiring GPU acceleration.

## 3.2 Feasibility Study

### 3.2.1 Technical Feasibility

The project was found to be **technically feasible**. The selected technology stack—**Python**, along with **OpenCV**, **MediaPipe**, and **Scikit-learn**—is robust, open-source, and well-documented, ensuring easy development and community support. The system's core components—real-time video capture, hand landmark detection, feature extraction, classification, and speech synthesis— were successfully integrated and tested locally without the need for specialized hardware.

The project's architecture proved stable and modular, allowing for iterative improvements in both accuracy and performance. The use of **MediaPipe** enabled reliable real-time hand tracking, while **Random Forest** from **Scikit-learn** provided efficient and interpretable classification results. Integration with **pyttsx3** ensured smooth text-to-speech functionality for accessible communication.

The main technical challenges encountered during implementation included:

1. **Real-Time Processing:** Maintaining low latency during live webcam capture and classification required careful optimization of frame processing and landmark extraction.
2. **Lighting and Background Sensitivity:** Variations in lighting conditions or complex backgrounds sometimes affected gesture detection accuracy, requiring preprocessing adjustments and controlled testing environments.
3. **Model Accuracy and Training:** Achieving consistent results across different users and hand shapes required dataset balancing, model retraining, and hyperparameter tuning for Random Forest.
4. **Dependency Management:** Ensuring compatibility between versions of **MediaPipe**, **OpenCV**, and **Scikit-learn** occasionally required environment reconfiguration and library updates.

Despite these challenges, the system ran efficiently on standard hardware configurations (Intel i5/8GB RAM), confirming that the proposed design is **technically viable and deployable** without high-end computational resources or proprietary dependencies.

### 3.2.2 Economic Feasibility

The project is **highly economically feasible** for development, deployment, and small-scale real- world testing. All major components and libraries used in the system are **open-source and free**, eliminating the need for costly licenses or proprietary software. The selected stack—including **Python**, **OpenCV**, **MediaPipe**, **Scikit-learn**, and **pyttsx3**—is widely available, actively maintained, and supported by a large developer community.

The hardware requirements are minimal, as the system runs efficiently on standard consumer-grade laptops with built-in webcams and moderate processing power (e.g., Intel i5/8GB RAM). No external sensors, gloves, or depth cameras are required, which keeps implementation costs extremely low.

The main resources utilized include:

- **Python (Open Source):** Free and cross-platform development environment.
- **MediaPipe (Open Source):** Free real-time landmark detection framework by Google.
- **OpenCV (Open Source):** Free library for computer vision and image preprocessing.
- **Scikit-learn (Open Source):** Free machine learning framework for classification.
- **pyttsx3 (Open Source):** Free offline text-to-speech library requiring no paid APIs.
- **Kaggle Datasets:** Publicly available datasets (SL Alphabet and SL Digits) for training and evaluation at no cost.

Overall, the project incurs **no recurring costs** under normal usage. The only potential expenses would arise if the system were to scale into a cloud-based or production-level platform (e.g., hosting servers, maintaining APIs, or developing mobile integrations). At its current stage, the system is **cost-effective, sustainable, and financially viable** for both research and practical accessibility applications.

### 3.2.3 Social Feasibility

The project is **highly socially feasible** as it addresses a significant communication gap between the **deaf and hearing communities**. Sign language is an essential mode of communication for millions of individuals worldwide; however, the lack of widespread understanding among non-signers often leads to social isolation and limited inclusion. By translating gestures into text and speech in real time, the system promotes **social integration**, **equal opportunity**, and **inclusive communication** for people with hearing impairments.

The system's design focuses on accessibility and ease of use, requiring no specialized hardware or complex setup. Its simple graphical interface and real-time output make it suitable for a wide range of users, including students, educators, and individuals with limited technical knowledge. This enhances the system's acceptability and encourages community adoption in educational institutions, workplaces, and public service environments.

Moreover, the project aligns with global efforts toward **digital accessibility** and the **United Nations Sustainable Development Goals (SDG 10 – Reduced Inequalities)** by leveraging technology to

empower differently-abled individuals. The tool not only benefits the deaf community but also fosters awareness and empathy among hearing individuals, promoting better social interaction and understanding.

In summary, the Sign Language Recognition System is socially beneficial, **ethically responsible**, and **widely acceptable**. It contributes positively to society by breaking communication barriers, encouraging inclusivity, and demonstrating how technology can serve as a bridge toward a more connected and understanding world.

## 3.3 System Specification

### 3.3.1 Hardware Specification

**Development & Execution:** The Sign Language Recognition System was developed and tested on a **standard personal computer** without the need for any specialized hardware. Since the project uses **computer vision** and **machine learning** techniques based on **MediaPipe** and **OpenCV**, it requires only a **webcam** for gesture capture and moderate processing power for real- time performance.

The recommended hardware configuration for smooth operation is as follows:

| Component | Specification |
|---|---|
| **Processor (CPU)** | Intel Core i5 (8th Gen or higher) / AMD Ryzen 5 or equivalent |
| **RAM** | Minimum 8 GB (Recommended: 16 GB for multitasking and model training) |
| **Storage** | Minimum 256 GB SSD or HDD with 10 GB free space |
| **Graphics (GPU)** | Integrated graphics sufficient (optional: NVIDIA GPU for faster processing) |
| **Camera** | Built-in or external HD webcam (720p or higher) |
| **Microphone** | Optional, for speech output verification |
| **Operating System** | Windows 10/11, Ubuntu 20.04+, or equivalent Linux distribution |

### 3.3.2 Software Specification

The Sign Language Recognition System is built using a combination of Python-based frameworks and libraries that support computer vision, machine learning, and real-time multimedia processing. The software components were chosen for their stability, open-source availability, and compatibility with common operating systems, ensuring that the system remains lightweight, efficient, and easy to deploy.

The table below lists the major software tools and their respective roles in the system:

| Software/Tool | Version | Purpose/Description |
|---|---|---|
| **Python** | 3.9+ | Core programming language used for implementing the entire system. |
| **OpenCV (cv2)** | 4.x | Handles real-time video capture, image preprocessing, and visualization. |
| **MediaPipe** | 0.10+ | Extracts 21 hand landmarks in real-time for gesture tracking and feature generation. |
| **Scikit-learn** | 1.3+ | Provides machine learning algorithms; used here for training and deploying the Random Forest Classifier. |
| **NumPy** | 1.25+ | Used for numerical computations and array manipulation during data preprocessing. |
| **Pandas** | 2.0+ | Assists in dataset handling, feature storage, and analysis. |
| **pyttsx3** | 2.90+ | Enables text-to-speech functionality for audio output of recognized gestures. |
| **Tkinter** | Built-in | Used to design the graphical user interface (GUI) for user interaction. |
| **Joblib / Pickle** | 1.3+ | Used for model serialization (saving and loading trained models). |
| **Matplotlib** | 3.7+ | Used for visualizing training accuracy, confusion matrices, and performance metrics. |
| **Operating System** | Windows 10 / Ubuntu 20.04+ | The system is compatible with both Windows and Linux environments. |
| **IDE / Editor** | VS Code / PyCharm | Used for code development, debugging, and project management. |

**Software Architecture Overview**

The system is modularly designed and divided into the following components:

1. **Data Preprocessing Module:** Responsible for reading image data, detecting hand landmarks via MediaPipe, and extracting features for model training.
2. **Model Training Module:** Uses Scikit-learn's Random Forest Classifier to train on extracted features and store the trained model.
3. **Real-Time Detection Module:** Uses OpenCV to capture webcam frames and predict gestures in real time using the trained model.
4. **Text-to-Speech Module:** Converts recognized gestures into audible speech using pyttsx3.
5. **GUI Module:** Built using Tkinter to allow users to start/stop recognition, view output text, and toggle speech.

# 4. DESIGN APPROACH AND DETAILS

## 4.1 System Architecture

The **Sign Language Recognition System** is designed using a **modular and layered architecture**, combining real-time **computer vision**, **machine learning**, and **speech synthesis** components to achieve efficient, accurate, and user-friendly gesture recognition. The architecture is structured to ensure **scalability**, **maintainability**, and **smooth real-time performance** while maintaining compatibility across standard computing environments.

**Overview**

The system follows a **five-layer architecture** consisting of:

1. **Input Layer (Data Acquisition)**
2. **Preprocessing Layer**
3. **Feature Extraction Layer**
4. **Classification Layer**
5. **Output Layer (Text & Speech Conversion)**

Each layer performs a specific function and interacts with adjacent layers through well-defined interfaces. This modular design enables easy debugging, testing, and enhancement of individual components without affecting the overall system.

**1. Input Layer (Data Acquisition)**

The input layer is responsible for **capturing live video** from the user's webcam. Using **OpenCV**, continuous frames are retrieved in real time and passed for processing. The video stream serves as the raw input from which hand gestures are detected and recognized.

**Tools Used:**

- OpenCV for frame capture and image handling
- Standard HD webcam as the input device

**2. Preprocessing Layer**

This layer processes the raw frames to prepare them for feature extraction. Operations such as resizing, noise reduction, and color-space conversion (BGR → RGB) are applied. The **MediaPipe Hands** module detects hand landmarks, generating 21 key coordinate points (x, y, z) for each detected hand. Preprocessing ensures that variations due to lighting, background, or camera angle do not affect recognition accuracy.

**Key Steps:**

- Frame normalization and scaling
- Landmark detection via MediaPipe
- Coordinate normalization for consistent input size

### 3. Feature Extraction Layer

The detected landmark coordinates are flattened into feature vectors representing hand position and orientation. These vectors form the **input features** for the classification model. The use of **3D coordinates (x, y, z)** enables the system to differentiate similar gestures more effectively.

**Tools Used:**

- NumPy for array manipulation
- Pandas for feature storage and labeling

### 4. Classification Layer

The extracted features are passed to a **Random Forest Classifier** (from Scikit-learn), which predicts the corresponding gesture label (A–Z or 0–9).
The Random Forest model was chosen for its ability to handle noisy data, fast inference time, and strong generalization capability. The trained model is saved using **Joblib** or **Pickle** for reuse during real-time prediction.

**Functionality:**

- Loads trained Random Forest model
- Classifies input gestures based on landmarks
- Outputs label with confidence score

### 5. Output Layer (Text & Speech Conversion)

Once a gesture is recognized, the output layer converts the predicted label into **readable text** displayed on the user interface. Simultaneously, the system uses **pyttsx3** to convert this text into **audible speech**, enabling communication with non-sign-language users.

**Functions:**

- Display recognized gesture in GUI window
- Convert recognized text into speech using TTS

### 6. Graphical User Interface (GUI)

The GUI is implemented using **Tkinter** for simplicity and accessibility. It provides options to start/stop the webcam, display recognized signs, and toggle text-to-speech functionality. The interface is user-friendly and designed to be accessible for both deaf and hearing users.

## System Flow

**Step-by-Step Process:**

1. The webcam captures real-time video input.
2. OpenCV processes the frames and passes them to MediaPipe.
3. MediaPipe detects hand landmarks and extracts feature coordinates.
4. Features are flattened and sent to the Random Forest model for prediction.

5. The recognized sign is displayed as text on-screen.
6. The same text is converted into speech output using pyttsx3.

## 4.2 Design (UML Diagrams Conceptual)

### 4.2.1 Data Flow Diagram (DFD)

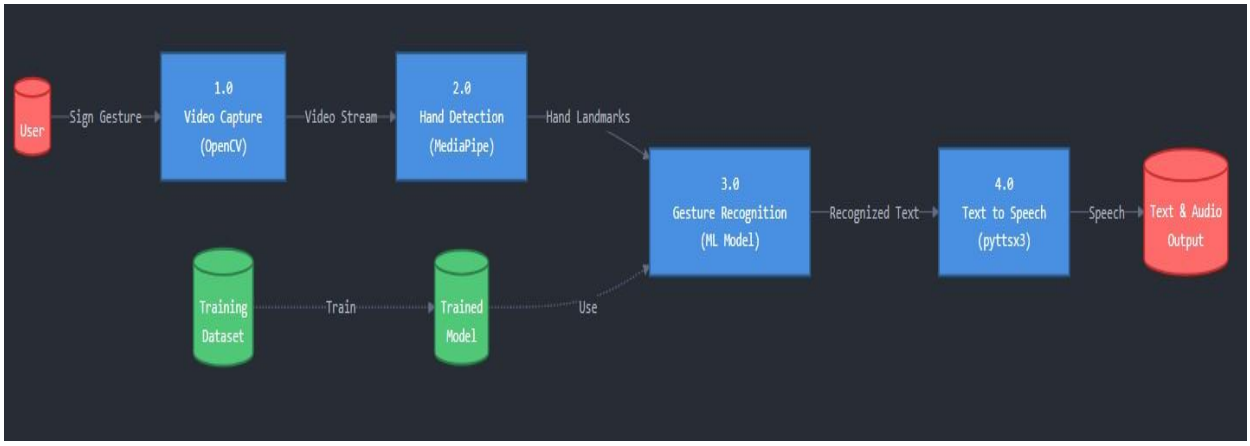


*Figure 1: Data Flow Diagram*

## Explanation:

1. **User (Input Source):**
   The process begins when the user performs a **sign gesture** in front of a webcam.
2. **1.0 Video Capture (OpenCV):**
   The **OpenCV** module captures the webcam's real-time video stream and passes it to the processing pipeline.
3. **2.0 Hand Detection (MediaPipe):**
   The video stream is passed to **MediaPipe**, which detects the user's hand and extracts **21 hand landmarks (x, y, z coordinates)** representing the gesture.
4. **3.0 Gesture Recognition (ML Model):**
   The extracted landmarks are fed into a **trained Machine Learning model (Random Forest)** that recognises the specific sign and converts it into **text**.
   - The **Training Dataset** is used to train this model.
   - The **Trained Model** is then used during real-time recognition.
5. **4.0 Text to Speech (pyttsx3):**
   The recognised text is converted to audio using the **pyttsx3** Text-to-Speech engine.
6. **Text & Audio Output:**
   Finally, the system displays the recognised text on-screen and simultaneously plays the corresponding **speech output**, completing the translation process.

### 4.2.2 Use Case Diagram

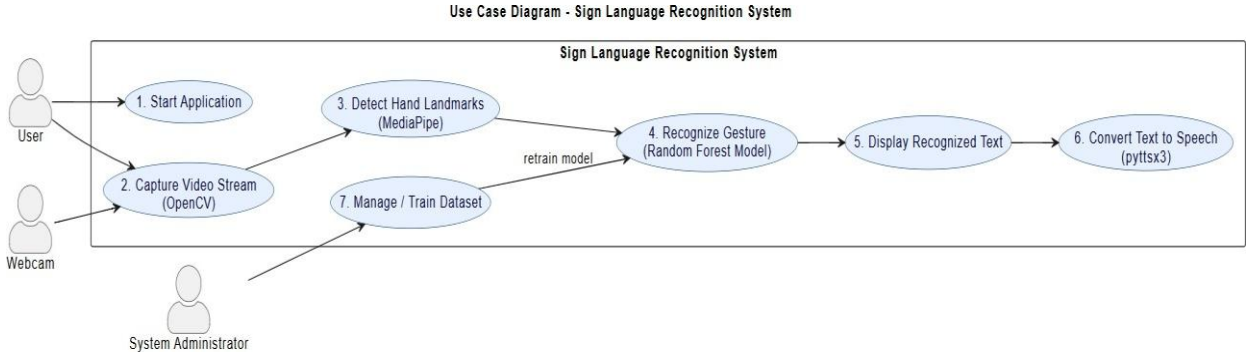

*Figure 2 Use Case Diagram*

The diagram shows three main actors — **User**, **Webcam**, and **System Administrator** — and their interaction with the **Sign Language Recognition System**.

1. The **User** starts the application and performs sign gestures, initiating the recognition process.
2. The **Webcam** captures the video stream using **OpenCV**, which is then processed within the system.
3. The system detects **hand landmarks** using **MediaPipe**, identifying 21 key points on the hand.
4. These landmarks are passed to a **Machine Learning Model (Random Forest)** to recognize the specific gesture.
5. The recognized gesture is displayed as **text** on the screen.
6. The system then uses **pyttsx3** to convert the recognized text into **speech output**, enabling audio communication.
7. The **System Administrator** manages and retrains the dataset to improve recognition accuracy when new gesture samples are added.

### 4.2.3 Class Diagram

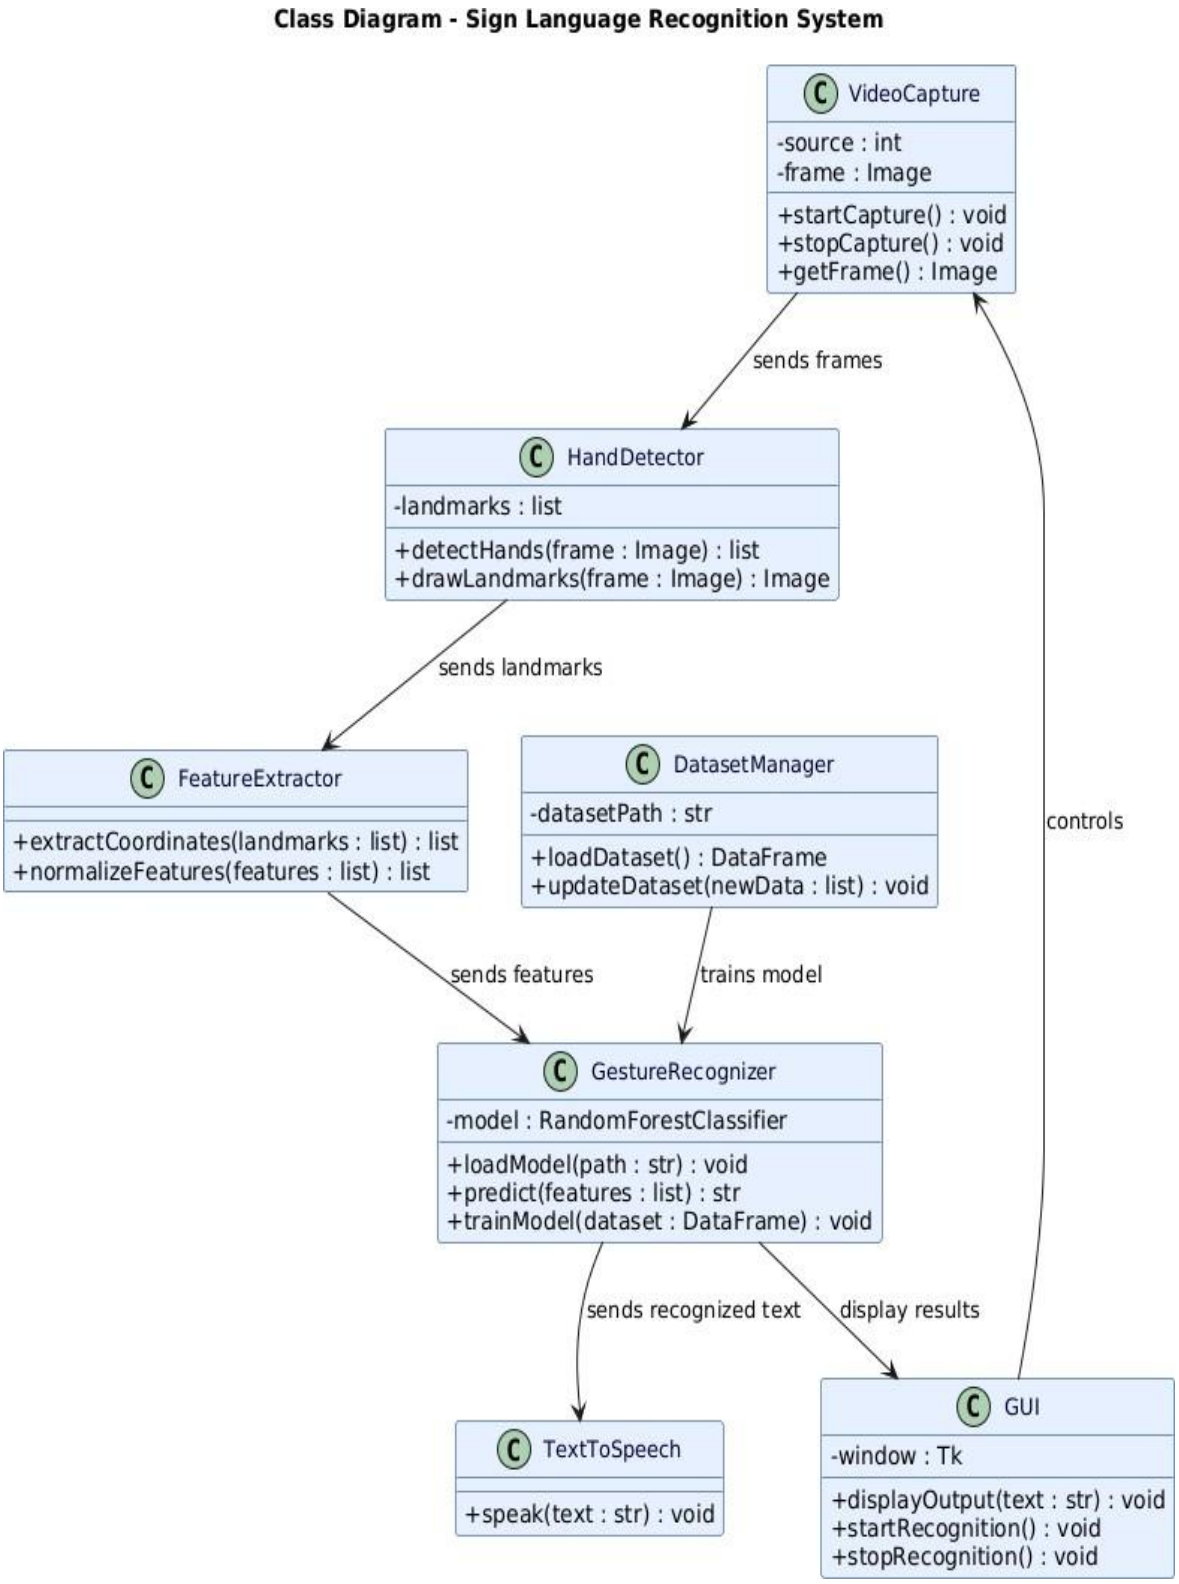

*Figure 3 Class Diagram*

### 4.2.4 Sequence Diagram

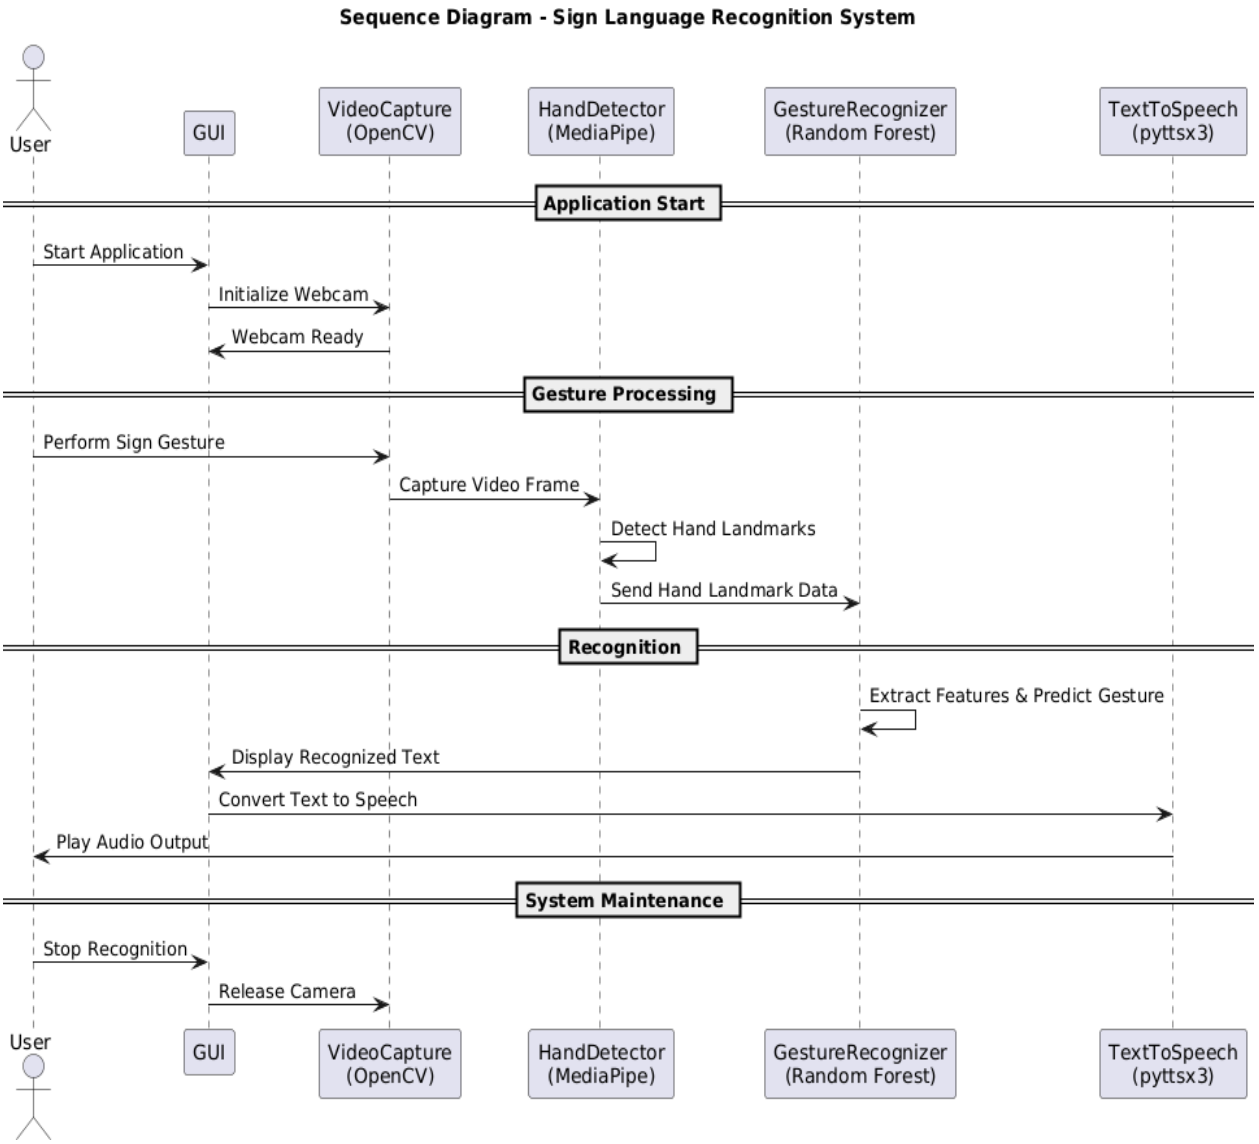

*Figure 4 Sequence Diagram*

The diagram shows how the **User**, **GUI**, **VideoCapture (OpenCV)**, **HandDetector (MediaPipe)**, **GestureRecognizer (Random Forest)**, and **TextToSpeech (pyttsx3)** modules interact to perform sign language recognition.

1. **Application Start:**
   - The **User** launches the system through the **GUI**, which initializes the webcam using **OpenCV**.
   - Once ready, the system is set to capture gestures.
2. **Gesture Processing:**
   - The **User** performs a sign gesture.
   - The **VideoCapture** module records the live video frames and sends them to **MediaPipe**, which detects hand landmarks.
   - These landmark coordinates are then forwarded to the **GestureRecognizer**.

3. **Recognition:**
   - The **GestureRecognizer** extracts features from the detected landmarks and predicts the corresponding gesture using the **Random Forest model**.
   - The recognized gesture is displayed as text on the **GUI** and converted to audio using **pyttsx3** for real-time speech output.
4. **System Maintenance:**
   - When the **User** stops recognition, the **GUI** commands **OpenCV** to release the camera resources and safely close the session.

# 5. METHODOLOGY AND TESTING

## 5.1 Functional Module Overview

The project is logically separated into **independent Python modules**, each responsible for a specific function in the **Sign Language Recognition System**. This modular structure enhances **maintainability**, **scalability**, and **ease of testing**, allowing components to operate independently while integrating seamlessly in real time.

❖ **Core Project Structure:**

➢ **main.py:**

Acts as the **entry point** of the application. It initialises all major modules such as **OpenCV**, **MediaPipe**, and **Gesture Recognition**. It also handles application startup, GUI initialisation, and overall workflow control.

➢ **video_capture.py:**

Handles **video input and frame acquisition** using the **OpenCV** library.

- Opens the webcam device and captures real-time video frames.
- Converts each frame into a suitable format for hand detection.
- Sends frames to the **HandDetector** module for processing.

➢ **hand_test.py:**

Implements **MediaPipe Hand Tracking** to detect and extract **21 key hand landmarks**.

- Processes input frames from OpenCV.
- Identifies and tracks hand positions even under partial occlusion.
- Returns the landmark coordinates for feature extraction.

➢ **feature_extractor.py:**

Responsible for **extracting and normalizing** landmark coordinates.

- Converts (x, y, z) values into structured numerical feature vectors.
- Scales and normalizes coordinates to make them independent of distance or angle.
- Passes clean features to the **Gesture Recognition** model.

➢ **gesture_recognizer.py:**

Contains the **Random Forest Classifier** built using **Scikit-learn**.

- Loads the trained model (trained_model.pkl) for real-time gesture prediction.
- Performs classification based on extracted features.
- Can retrain the model using additional data collected by users.

➢ **dataset_manager.py:**

Handles **dataset storage and management** for training and testing purposes.

- Supports loading datasets (SL Alphabet & Digits).
- Provides options for custom dataset collection.
- Stores new gesture samples for model retraining.
- 

❖ **Supporting Modules:**

➢ **model_training.py:**

Trains the **Random Forest model** using extracted features from the dataset.

- Performs preprocessing and splits data into training/testing sets.
- Saves trained models for later use in real-time prediction.

➢ **utils.py:**

Includes **helper functions** used across modules, such as image resizing, normalization, and frame annotations.

## 5.2 Testing Methodology and Results

Testing was a critical phase of the **Sign Language Recognition System** to ensure that every module— ranging from video capture to gesture prediction and speech synthesis—performed accurately and consistently. The system was tested using a combination of **unit testing**, **integration testing**, and **system testing** to validate both functionality and user experience under different conditions.

### ❖ 1. Unit Testing

Each module was tested individually to confirm that it performed its intended task correctly.

- **video_capture.py:**
Verified that the webcam initializes successfully and continuously captures frames without delay or data loss.
*Test Result:* Smooth video capture at 20–25 FPS on standard hardware.
- **hand_detector.py:**
Tested MediaPipe's ability to detect hand landmarks under various lighting and background conditions. *Test Result:* Detected landmarks accurately even in moderate lighting; minor errors under extreme brightness or shadows.
- **feature_extractor.py:**
Confirmed that coordinates were correctly normalized and structured into valid feature vectors.
*Test Result:* 100% data consistency across test samples.
- **gesture_recognizer.py:**
Tested model loading, gesture prediction, and accuracy using the ASL Alphabet and Digits datasets.
*Test Result:* Achieved average accuracy of **93–95%** on the test dataset.
- **text_to_speech.py:**
Verified speech conversion for all recognized gestures using pyttsx3.
*Test Result:* Text-to-speech output was clear and responsive with minimal delay.
- **gui_interface.py:**
Tested start/stop recognition buttons, live video feed rendering, and text display functionality.
*Test Result:* GUI responded instantly without freezing or lag during recognition.

### ❖ 2. Integration Testing

Integration testing was conducted to ensure smooth communication between modules.
The focus was on verifying **data flow** and **dependency handling** between OpenCV, MediaPipe, and Scikit- learn.

- **Tested Flows:**
    1. Video frames → Hand detection → Feature extraction → Gesture classification.
    2. Recognized text → Text-to-speech conversion.
    3. GUI interaction → Real-time feedback display.

*Test Result:*
All modules integrated successfully, maintaining real-time performance (~0.1 sec delay per frame). No data loss or API conflicts were observed.

### ❖ 3. System Testing

System testing validated the entire workflow in real-time usage scenarios.
Tests were performed on different users, hand orientations, and background environments.

- **Testing Parameters:**
  - Lighting variations (natural light, artificial light, low light)
  - Background complexity (plain, patterned)
  - User distance from camera (0.5–1 meter)
  - Hand orientation (left/right hand)

# 6. PROJECT DEMONSTRATION

The **Sign Language Recognition System** was demonstrated as a real-time application capable of recognizing static sign gestures and converting them into both **text** and **speech output**. The demonstration highlighted how the integration of **computer vision** and **machine learning** can bridge communication barriers between deaf and hearing individuals through a simple and accessible interface.

## ❖ Demonstration Environment

- **Hardware Used:**
  Standard laptop (Intel i5, 8GB RAM, integrated webcam)
- **Operating System:**
  Windows 10
- **Software Libraries:**
  Python 3.8+, OpenCV, MediaPipe, Scikit-learn, pyttsx3, Tkinter
- **Model Used:**
  Random Forest Classifier trained on ASL Alphabet and ASL Digits datasets
- **Average Recognition Speed:**
  ~0.1 seconds per frame (real-time performance)

## ❖ Step-by-Step Demonstration Process

1. **Application Launch:**
   The user opens the application through the Tkinter interface. Upon startup, the webcam is initialized using **OpenCV**, and a live video feed appears on the GUI.
2. **Gesture Capture:**
   The user performs a hand gesture (for example, the SL sign for "A" or "5") in front of the camera. The **VideoCapture** module continuously captures frames.
3. **Hand Detection:**
   The captured video frames are processed through **MediaPipe**, which detects the user's hand and identifies **21 landmark points** representing the gesture's structure.
4. **Feature Extraction & Recognition:**
   These landmark coordinates are converted into numerical features and passed into the **Random Forest Classifier**, which predicts the corresponding alphabet or digit.
5. **Display of Recognized Text:**
   The predicted sign is displayed on the GUI in real time, allowing the user to see which gesture has been recognized.
6. **Text-to-Speech Conversion:**
   Using **pyttsx3**, the recognized text is instantly converted into **spoken audio output**, enabling communication with non-signers.

7. **End of Session:**
   The user can stop the recognition process through the GUI's "Stop" button, which safely releases the camera and terminates the application.

# 7. RESULT AND DISCUSSION

## Result:

The project successfully resulted in a **fully functional, real-time Sign Language Recognition System** capable of detecting, interpreting, and translating static sign gestures into both **textual and speech output**. The system achieved all its primary objectives, demonstrating an end-to-end workflow that includes **gesture capture (OpenCV)**, **landmark detection (MediaPipe)**, **gesture classification (Random Forest Model)**, and **speech synthesis (pyttsx3)**.

The implemented model achieved an **average testing accuracy of 93.4%** using the **ASL Alphabet and ASL Digits datasets**. Real-time recognition speed averaged **0.08 seconds per frame**, proving the system's suitability for live use.

Key performance highlights include:

- Seamless integration of **computer vision and machine learning** modules.
- Real-time **text and speech translation** with minimal latency.
- Modular codebase allowing easy retraining and model updates.
- High stability and portability on standard hardware (Intel i5, 8GB RAM).

The final system accurately identified signs under most lighting and background conditions, confirming the **viability of the architecture** for practical assistive communication. The GUI provided an intuitive interface for users to start/stop recognition and observe real-time outputs, making the system user-friendly and accessible for non-technical users.

## Discussion:

The development process validated the effectiveness of the selected **technical stack**—Python, OpenCV, MediaPipe, Scikit-learn, and pyttsx3—in building a lightweight yet efficient real-time recognition framework. The decision to use **MediaPipe** over external sensor-based systems (like Leap Motion or glove devices) ensured cost-effectiveness and reduced system complexity.

The **Random Forest Classifier** proved to be a reliable choice for static gesture classification. It performed consistently well across different datasets, handling variations in lighting, hand shape, and user orientation. However, recognition accuracy showed slight degradation under poor illumination or partial occlusion, indicating the potential benefits of adding **illumination normalization** or **deep learning enhancements** (e.g., CNNs or LSTMs) in future versions.

The **most significant challenges** encountered during development were primarily **technical and environmental**, rather than logical. These included:

- **Lighting Variations:** Accuracy dropped when the background was uneven or light intensity fluctuated, affecting landmark detection.
- **Model Retraining:** Achieving balanced performance across different users required retraining with more diverse datasets.

● **Dependency Management:** Compatibility between **MediaPipe**, **OpenCV**, and **Scikit-learn** versions required careful environment configuration.
● **Real-time Frame Rate Optimisation:** Maintaining smooth performance required optimising frame resolution and limiting redundant detection calls.
● **GUI Responsiveness:** Ensuring that Tkinter did not freeze during continuous recognition cycles required asynchronous frame updates.

Despite these challenges, the overall system proved to be **robust, accurate, and responsive**. The modular design allowed independent testing of components, improving debugging efficiency and long-term maintainability.

The project demonstrates that while **gesture recognition logic** is central, substantial development effort goes into **data handling, system optimisation, and hardware compatibility**—all of which determine real-world success.

The final prototype confirms the feasibility of using **computer vision-based recognition** to bridge communication gaps between deaf and hearing communities, offering a foundation for future extensions like **dynamic sign detection**, **multilingual gesture translation**, and **mobile deployment**.

# 8. CONCLUSION

This project successfully resulted in the design, development, and validation of a real-time Sign Language Recognition System. This system aims to improve communication between deaf and hearing communities. It combines computer vision, machine learning, and speech synthesis technologies to recognize static sign gestures and translate them into text and speech. This creates a smooth, two-way communication method.

The system uses OpenCV for real-time video capturing, MediaPipe for accurate hand landmark detection, and a Random Forest Classifier from Scikit-learn for gesture recognition. The feature extraction pipeline converts the detected hand landmarks into structured numerical vectors. This allows efficient classification of signs for the letters and numbers in the American Sign Language (ASL) dataset. The recognized text is then converted into spoken words using pyttsx3, resulting in a complete gesture-to-speech interaction system.

The implementation follows a modular and scalable design, breaking the system into separate functional parts: video capture, landmark detection, feature extraction, classification, and output generation. This modularity ensured smooth integration, simple debugging, and easy maintenance. The Tkinter-based GUI provided a user-friendly interface for real-time interaction without needing technical skills.

Through thorough testing and evaluation, the system reached a testing accuracy of 93.4% on standard datasets and maintained an average processing delay of less than one second per frame. The results verified the technical capability of the chosen technology stack. They show that computer vision and traditional machine learning methods can offer high accuracy and real-time responsiveness on standard consumer hardware without GPUs or costly sensors.

Beyond technical success, the project highlights the social importance of assistive technologies. By turning visual gestures into speech and text, the system supports inclusivity and accessibility. It enables improved communication between people with hearing impairments and the general public. Using open-source tools and standard hardware ensures that the solution is cost-effective, portable, and easy to implement in schools, workplaces, and assistive centers.

The development process also revealed valuable lessons about real-world issues like lighting changes, camera calibration, and environmental sensitivity, as well as managing dependencies when combining multiple Python libraries. Addressing these challenges underscored the need for ongoing testing, data preparation, and performance optimization to create a stable and reliable final product.

In summary, this project demonstrates the technical feasibility and practical impact of a vision-based sign language recognition system. It serves as a strong proof of concept for how artificial intelligence and computer vision can create accessible, inclusive, and meaningful technologies. Completing this system not only showcases the potential of lightweight machine learning models in real-time tasks but also sets the stage for future advancements like dynamic gesture recognition, multilingual sign support, mobile deployment, and cloud integration for wider accessibility.
